EXP: 01

Implement a simple deep neural network (DNN) for solving the polynomial equation with the following specifications:

a) Use three hidden-layers of sizes 32, 64, and 128 and display the generated DNN with the required number of parameters.
b) Generate training samples within the range of -20 to +20. Use an appropriate method for normalizing the training data in the range of -1 to +1.
c) Use 10% of the samples as test data and 10% of the samples as validation data and the rest of the data for training the DNN with an appropriate number of epochs.
d) Display the training accuracy vs validation accuracy and training error vs validation error curves.

Regression: Finding a relationship between things so that we can predict a numerical value.
